

Requirements for inventory system:

The inventory system consists of many different products. Each product has a product id, name, cost, and quantity. The products are stored in various warehouses. Each warehouse is identified with a warehouse id, name, and location; duplicate products may not be stored in different warehouses, e.g. product 1 can only be stored in one warehouse.

The products in each warehouse are developed by using various parts. Each part has a unique id and a name. The parts can be associated with many different products in the inventory system. Parts must be related to a product in order to exist in the system.

Each warehouse has employees who work at that location. Each employee can only work at one warehouse location. The employees can be identified with a unique id, name, and salary.
